# Notation

This section provides a concise reference describing notation as used in the book by ?. If you are unfamiliar with any of the corresponding mathematical concepts, ? describe most of these ideas in chapters 2–4.

## Numbers and Arrays

$a$	A scalar (integer or real)
$\mathbf{a}$	A vector
$\mathbf{A}$	A matrix
$\mathbf{A}$	A tensor
$\mathbf{I}_n$	Identity matrix with $n$ rows and $n$ columns
$\mathbf{I}$	Identity matrix with dimensionality implied by context
$\mathbf{e}^{(i)}$	Standard basis vector $[0, \dots, 0, 1, 0, \dots, 0]$ with a 1 at position $i$
$\text{diag}(\mathbf{a})$	A square, diagonal matrix with diagonal entries given by $\mathbf{a}$
$\mathbf{a}$	A scalar random variable
$\mathbf{a}$	A vector-valued random variable
$\mathbf{A}$	A matrix-valued random variable

## Sets and Graphs

$\mathbb{A}$	A set
$\mathbb{R}$	The set of real numbers
$\{0, 1\}$	The set containing 0 and 1
$\{0, 1, \dots, n\}$	The set of all integers between 0 and $n$
$[a, b]$	The real interval including $a$ and $b$
$(a, b]$	The real interval excluding $a$ but including $b$
$\mathbb{A} \setminus \mathbb{B}$	Set subtraction, i.e., the set containing the elements of $\mathbb{A}$ that are not in $\mathbb{B}$
$\mathcal{G}$	A graph
$Pa_{\mathcal{G}}(\mathbf{x}_i)$	The parents of $\mathbf{x}_i$ in $\mathcal{G}$

## Indexing

$a_i$	Element $i$ of vector $\mathbf{a}$ , with indexing starting at 1
$a_{-i}$	All elements of vector $\mathbf{a}$ except for element $i$
$A_{i,j}$	Element $i, j$ of matrix $\mathbf{A}$
$\mathbf{A}_{i,:}$	Row $i$ of matrix $\mathbf{A}$
$\mathbf{A}_{:,i}$	Column $i$ of matrix $\mathbf{A}$
$A_{i,j,k}$	Element $(i, j, k)$ of a 3-D tensor $\mathbf{A}$
$\mathbf{A}_{:,:,i}$	2-D slice of a 3-D tensor
$\mathbf{a}_i$	Element $i$ of the random vector $\mathbf{a}$

## Linear Algebra Operations

$\mathbf{A}^\top$	Transpose of matrix $\mathbf{A}$
$\mathbf{A}^+$	Moore-Penrose pseudoinverse of $\mathbf{A}$
$\mathbf{A} \odot \mathbf{B}$	Element-wise (Hadamard) product of $\mathbf{A}$ and $\mathbf{B}$
$\det(\mathbf{A})$	Determinant of $\mathbf{A}$

## Calculus

$\frac{dy}{dx}$	Derivative of $y$ with respect to $x$
$\frac{\partial y}{\partial x}$	Partial derivative of $y$ with respect to $x$
$\nabla_{\mathbf{x}}y$	Gradient of $y$ with respect to $\mathbf{x}$
$\nabla_{\mathbf{X}}y$	Matrix derivatives of $y$ with respect to $\mathbf{X}$
$\nabla_{\mathbf{X}}y$	Tensor containing derivatives of $y$ with respect to $\mathbf{X}$
$\frac{\partial f}{\partial \mathbf{x}}$	Jacobian matrix $\mathbf{J} \in \mathbb{R}^{m \times n}$ of $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$
$\nabla_{\mathbf{x}}^2 f(\mathbf{x})$ or $\mathbf{H}(f)(\mathbf{x})$	The Hessian matrix of $f$ at input point $\mathbf{x}$
$\int f(\mathbf{x})d\mathbf{x}$	Definite integral over the entire domain of $\mathbf{x}$
$\int_{\mathbb{S}} f(\mathbf{x})d\mathbf{x}$	Definite integral with respect to $\mathbf{x}$ over the set $\mathbb{S}$

## Probability and Information Theory

$a \perp b$	The random variables a and b are independent
$a \perp b   c$	They are conditionally independent given c
$P(a)$	A probability distribution over a discrete variable
$p(a)$	A probability distribution over a continuous variable, or over a variable whose type has not been specified
$a \sim P$	Random variable a has distribution $P$
$\mathbb{E}_{x \sim P}[f(x)]$ or $\mathbb{E}f(x)$	Expectation of $f(x)$ with respect to $P(x)$
$\text{Var}(f(x))$	Variance of $f(x)$ under $P(x)$
$\text{Cov}(f(x), g(x))$	Covariance of $f(x)$ and $g(x)$ under $P(x)$
$H(x)$	Shannon entropy of the random variable x
$D_{\text{KL}}(P \  Q)$	Kullback-Leibler divergence of P and Q
$\mathcal{N}(\mathbf{x}; \boldsymbol{\mu}, \boldsymbol{\Sigma})$	Gaussian distribution over $\mathbf{x}$ with mean $\boldsymbol{\mu}$ and covariance $\boldsymbol{\Sigma}$

## Functions

$f : \mathbb{A} \rightarrow \mathbb{B}$  The function  $f$  with domain  $\mathbb{A}$  and range  $\mathbb{B}$

$f \circ g$  Composition of the functions  $f$  and  $g$

$f(\mathbf{x}; \boldsymbol{\theta})$  A function of  $\mathbf{x}$  parametrized by  $\boldsymbol{\theta}$ . (Sometimes we write  $f(\mathbf{x})$  and omit the argument  $\boldsymbol{\theta}$  to lighten notation)

$\log x$  Natural logarithm of  $x$

$\sigma(x)$  Logistic sigmoid,  $\frac{1}{1 + \exp(-x)}$

$\zeta(x)$  Softplus,  $\log(1 + \exp(x))$

$\|\mathbf{x}\|_p$   $L^p$  norm of  $\mathbf{x}$

$\|\mathbf{x}\|$   $L^2$  norm of  $\mathbf{x}$

$x^+$  Positive part of  $x$ , i.e.,  $\max(0, x)$

$\mathbf{1}_{\text{condition}}$  is 1 if the condition is true, 0 otherwise

Sometimes we use a function  $f$  whose argument is a scalar but apply it to a vector, matrix, or tensor:  $f(\mathbf{x})$ ,  $f(\mathbf{X})$ , or  $f(\mathbf{X})$ . This denotes the application of  $f$  to the array element-wise. For example, if  $\mathbf{C} = \sigma(\mathbf{X})$ , then  $C_{i,j,k} = \sigma(X_{i,j,k})$  for all valid values of  $i$ ,  $j$  and  $k$ .

## Datasets and Distributions

$p_{\text{data}}$	The data generating distribution
$\hat{p}_{\text{data}}$	The empirical distribution defined by the training set
$\mathbb{X}$	A set of training examples
$\mathbf{x}^{(i)}$	The $i$ -th example (input) from a dataset
$y^{(i)}$ or $\mathbf{y}^{(i)}$	The target associated with $\mathbf{x}^{(i)}$ for supervised learning
$\mathbf{X}$	The $m \times n$ matrix with input example $\mathbf{x}^{(i)}$ in row $\mathbf{X}_{i,:}$

## 1 Introduction

Parkinson's disease (PD) is the second most common neurodegenerative disease after Alzheimer's disease [1]. It is expected to impose an increasing social and economic burden on societies as populations age [2]. The prevalence of PD in industrialized countries is about 1% in people over 60 years of age [2]. The standardized incidence rate of PD is estimated to range between about 10 and about 20 per 100,000 person-years [2]. Thus, this results in the diagnosis of up to 100,000 new PD cases annually in the EU and up to 50,000 cases in the US.

PD is characterized by bradykinesia and variable expression of cardinal symptoms: resting tremor, rigidity, and postural instability [3, 4]. However, this combination of symptoms, often referred to as 'parkinsonism' or 'parkinsonian syndrome' (PS), occurs not only in PD (and some rare 'atypical' neurodegenerative PS such as multiple system atrophy, progressive supranuclear palsy and corticobasal degeneration). It also occurs in so-called 'secondary' (non-neurodegenerative) PS that can be induced by drugs, head trauma, inflammatory or metabolic disorder, as well as other diseases such as essential tremor, dystonic tremor, or normal pressure hydrocephalus [3, 5]. A particularly frequent cause of secondary PS is cerebrovascular disease [6]. The differentiation between PD and secondary PS is highly relevant, because secondary PS might be treated more effectively than PD and some secondary PS may be fully cured. Yet, the clinical, that is, symptom-based differentiation between PD and secondary PS is challenging in a significant fraction of patients, particularly at early disease stages with mild symptoms and in patients with atypical presentation [7, 8]. These cases are often referred to as 'clinical uncertain parkinsonian syndromes' (CUPS) [9].

DAT-SPECT with [<sup>123</sup>I]FP-CIT is an established nuclear medicine brain imaging procedure for Parkinson's disease diagnosis. The wide usage of the procedure is due to its high accuracy, its relevant impact on patient management, and the strong guideline recommendations. In Europe about 70,000 patients are referred to DAT-SPECT per year, in Germany alone about 10,000, at UK currently about 400 per year [22]. The demographical change in industrial countries is expected to result in a further increase in the number of DAT-SPECT examinations, because age is the major risk factor for PD [23]. Furthermore, there are early signs of PD such as smell loss and *idiopathic* rapid eye movement sleep and behavioral disorder that can precede movement problems by several years, but are not particularly specific for PD [24-26]. It becomes increasingly important to detect PD at these early pre-motor stages, because the earlier the treatment is initiated the better the chances of moderating the course of PD with disease-modifying drugs[27].

In clinical practice, the interpretation of DAT-SPECT is binary, that is, the nuclear medicine physician has to decide whether the SPECT images indicate degeneration of the dopaminergic neurotransmitter system (Parkinson's disease) or not (secondary PS). This decision can be challenging by visual inspection of the tomographic SPECT images, particularly for less experienced readers [28]. Thus, DAT-SPECT would benefit from methods for the automatic classification of the images

that achieve similar (or better) performance as experienced readers. Convolutional neural networks (CNNs) appear particularly promising for this purpose [29-47].

Yet, there are also ‘true’ borderline cases that cannot be classified with high certainty even by expert readers. In DAT-SPECT of CUPS, the proportion of visually inconclusive borderline cases ranges between 5 and 10% [48, 49]. Automatic binary classification of these cases by a CNN might pretend a certainty of the diagnosis that is not actually given. It is important, therefore, to identify these cases in order to make sure that the user visually inspects these SPECT images in order to check the automatic categorization particularly carefully. The user will accept the CNN’s decision in some case, overrule the CNN in other cases, and will categorize the remaining cases as actually inconclusive (and might recommend follow-up DAT-SPECT after 6-12 months [50]).

The most obvious approach to identify borderline cases in CNN-based classification would be based on the distance of the CNN’s sigmoid output from a predefined decision threshold (e.g., 0.5). However, empirically, sigmoid outputs of CNN for classification of DAT-SPECT tend to cluster at the extreme values so that their utility for the identification of borderline cases seems limited. As a consequence, this approach is not recommended among practitioners, as it tends to overestimate the certainty of CNN-based classification [51-53].

Against this background, the current work aimed to propose and validate a CNN-based approach for the automatic classification of DAT-SPECT that allows reliable identification of inconclusive cases that might be misclassified by the CNN when the decision threshold is strictly applied. The ‘decision confidence’ of the classifier is evaluated on a metric, proposed in the following, that aims to maximize the performance of the classifier on between-reader consensus cases while minimizing the potential effort of manual inspection originating from inconclusive cases.

Starting from the assumption that between-readers discrepancy in the binary visual interpretation of DAT-SPECT is much more likely in inconclusive cases than in conclusive cases, a standard CNN structure was trained for automatic classification of DAT-SPECT using a large training dataset in which each SPECT image had been visually classified by three independent readers. During the model training phase, the standard-of-truth label was selected randomly from the three independent available reads. This way, the same inconclusive image could be presented to the network with different standard-of-truth labels. The rationale was that this could allow the network to learn about the uncertainty of these cases, and that this would result in sigmoid outputs close to the decision threshold.

This “random label” training (RLT) approach was compared with the conventional majority vote training (MVT) approach. In the latter, the majority vote across the three readers was consistently used as standard-of-truth during the training phase. The MVT obviously “hides” the uncertainty associated with between-readers discrepancy from the network.

To be able to better assess the performance of the CNN-based approaches, univariate and multivariate conventional methods were employed as benchmark methods.

In addition, the performance of the approaches is also evaluated on independent external datasets.

The primary hypothesis put to test in this work was that the sigmoid output of the CNN is more appropriate for the identification of inconclusive cases (by an ‘inconclusive’ range around the decision threshold) when the network is trained with the RLT approach compared to MVT.

To test this hypothesis, the proportion of inconclusive cases required to achieve a given balanced accuracy in the conclusive cases was proposed and used as a performance metric. More precisely, the area under the curve (AUC) of balanced accuracy in conclusive cases versus the proportion of inconclusive cases (observed in the test set) was used as a model-agnostic quality metric. The AUC does not depend on a specific working point (target balanced accuracy). The rationale for this performance metric is that more inconclusive cases would require more attention and manual inspection by the attending physician which is considered ‘expensive’ (“90% inconclusive cases to achieve the required accuracy in the remaining 10% of cases is clearly useless”). Therefore the utility of the classifier for widespread use in clinical practice depends on its ‘decision confidence’, e.g. the proportion of inconclusive cases to be accepted to achieve a predefined balanced accuracy in the remaining conclusive cases.

The following secondary hypotheses were put to test. First, CNN-based classification outperforms conventional methods in terms of balanced accuracy, both univariate and multivariate conventional methods. The specific binding ratio (SBR) of the tracer uptake in the putamen was used for the univariate analyses. Current procedure guidelines recommend the putaminal SBR to support the visual interpretation of DAT-SPECT in everyday clinical patient care [54]. The putaminal SBR characterizes the contrast of the tracer uptake (= intensity) in the putamen relative to the mean tracer uptake in a reference region void of DAT [55]. The putaminal SBR is assumed to be proportional to the density of DAT in the putamen [55]. As a multivariate benchmark method, a random forest approach was implemented using the expression profile of a set of covariance patterns as input. The covariance patterns were identified by principal component analysis in the training dataset.

Second, CNN-based classification demonstrates enhanced generalizability, such as being more robust regarding varying image characteristics (e.g., spatial resolution) associated with the use of different acquisition hardware (different SPECT cameras, different collimators...) and different reconstruction and correction methods (application of resolution recovery, application of attenuation correction...). To test this hypothesis, the classification methods were compared in two test datasets fully independent of the training dataset.

The following research questions are addressed:

- When comparing the CNN-based approaches, how does the RLT approach perform compared to the MVT approach? Is the performance metric proposed in this work practically suitable for the comparison of different approaches?

- How do the CNN-based approaches perform on diverse testing data compared to conventional approaches? What conclusions can be made regarding the generalizability of the approaches under test?

## 2 Background

### 2.1 DAT-SPECT for diagnosing PD

PD, as well as the ‘atypical’ neurodegenerative PS, is associated with progressive loss of substantia nigra pars compacta (SNpc) dopaminergic neurons projecting to the striatum [10]. Reduced availability of dopamine transporters (DAT) in the striatum is well-validated as a biomarker for nigrostriatal degeneration in PD [11-13]. It can be detected by single photon emission computed tomography (SPECT) with dopamine transporter (DAT) ligands [14, 15]. Reduction of striatal DAT availability is strongly advanced already at the earliest symptomatic (motor) stages of PD, because the degeneration of dopaminergic nerve endings in the striatum is an early step in the pathological PD cascade [11-13]. Compensatory downregulation of the DAT expression in the remaining nerve endings results in even more pronounced striatal DAT loss [16-18]. Secondary PS are as a rule not associated with nigrostriatal degeneration and loss of striatal DAT. To differentiate PD from secondary PS based on striatal DAT availability, the radioactively labeled DAT ligand [<sup>123</sup>I]FP-CIT (trade name: DaTscan<sup>®</sup>) has been licensed as SPECT tracer in both, the US and Europe [19].

A recent review, including a non-systematic meta-analysis, of DAT-SPECT with [<sup>123</sup>I]FP-CIT in PS confirmed high sensitivity (median 93%) and high specificity (median 89%) of DAT-SPECT for the differentiation of PD from secondary PS in patients with CUPS [20]. The review further revealed that DAT-SPECT leads to a change of diagnosis in about 40% and to a change of treatment in about the same proportion of patients with CUPS [20]. Thus, DAT-SPECT with [<sup>123</sup>I]FP-CIT is highly diagnostically accurate and has a relevant impact on the diagnosis and treatment of CUPS patients. Guidelines from professional neurological societies therefore strongly strengthened the role of DAT-SPECT with [<sup>123</sup>I]FP-CIT in the last years [21]. For example, the current version of the S3 guideline “Idiopathic Parkinson syndrome” of the German Society of Neurology states that DAT-SPECT *should* be performed at an early disease stage in CUPS.

## 2.2 Methods for classification

# 3 Methods

## 3.1 Development Data Preparation

In the following, the data preparation techniques applied to the development dataset are explained in detail.

### 3.1.1 Data Preprocessing

Individual DAT-SPECT images were stereotactically normalized to the anatomical space of the Montreal Neurological Institute (MNI) using the Normalize tool of the Statistical Parametric Mapping software package (version SPM12) and a set of custom DAT-SPECT templates representative of normal and different levels of Parkinson-typical reduction of striatal uptake as target [73]. The voxel size of the stereotactically normalized images was  $2 \times 2 \times 2 \text{ mm}^3$ . Intensity normalization was achieved by voxelwise scaling to the individual 75th percentile of the voxel intensity in a reference region comprising the whole brain without striata, thalamus, brainstem, cerebellum, and ventricles [74]. The resulting images are distribution volume (DVR) images. A 2-dimensional transversal DVR slab of 12mm thickness and 91x109 pixels with 2 mm edge length was obtained by averaging 6 transversal slices through the striatum [75].

### 3.1.2 Data Augmentation

Data augmentation was applied to the development dataset to increase the heterogeneity of the data. To enhance robustness across various attenuation correction and scatter correction methods, each image was generated both with and without applying attenuation and scatter corrections. Also 3D-smoothing was employed for augmentation using an isotropic Gaussian kernel with various Full Width at Half Maximum (FWHM) values (FWHM = 10, 12, 14, 16, 18mm). Thereby an augmented dataset of 20,880 images in total was constructed based on 1,740 cases. An example of two cases augmented using the described techniques is depicted in Figure 1.

### 3.1.3 Dataset Splitting

The augmented development dataset was split into three subsets: train set (60%), validation set (20%) and test set (20%). While splitting the data it was ensured that the augmented images belonging to a concrete patient were put only into one subset. Thereby inter-subset data leakage was prohibited. Ten different random splits were created to train and test each of the methods.

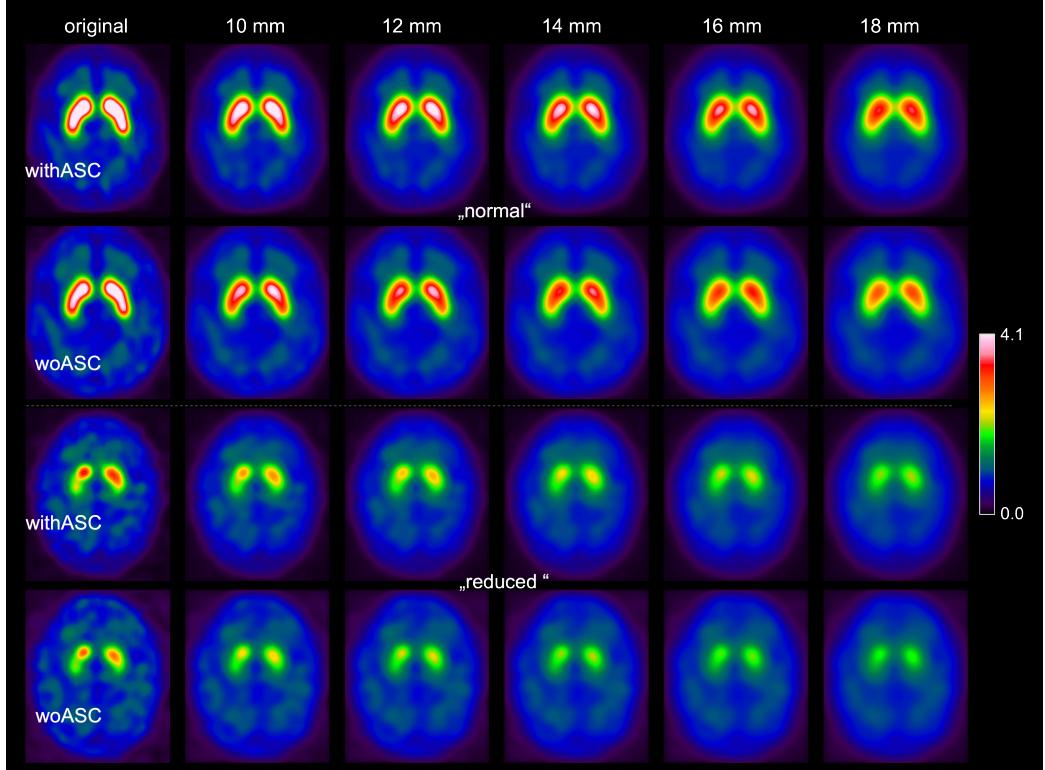

Figure 1: Images obtained through augmentation of two sample cases from the development dataset, a healthy case (above) and a PD case with reduced availability of DAT in the striatum (below).

### 3.2 Univariate benchmark: Specific Binding Ratio

The unilateral [ $^{123}\text{I}$ ]FP-CIT specific binding ratio (SBR) method was used as the main benchmark. Here, the SBR in left and right putamen was obtained by hottest voxels (HV) analysis of the stereotactically normalized DVR image using large unilateral putamen masks predefined in MNI space [46]. It can be calculated as

$$\text{HV-SBR}_{\text{unilateral}} = \frac{1}{K} \sum_k \hat{I}_{k,ROI} , \quad (1)$$

where  $\hat{I}_{k,ROI}$  are the *normalized* voxel intensities of the  $K$ -hottest voxels of the unilateral ROI. The voxel intensities of the hottest voxels are normalized to the 75th percentile of the voxel intensities in the reference region associated with non-specific binding [46]. The minimum of the HV-SBR values from the left and right hemispheres was used for the analysis. An in-depth description of the unilateral SBR method can be found in [46].

### 3.3 Multivariate benchmark: PCA-enhanced Random Forest

### 3.4 CNN-based classification - MVT and RLT

## 4 Data Sources

The study retrospectively included 3 different datasets with a total of 3025 DAT-SPECT images. The primary dataset (“development dataset”) was used for both training and testing the models associated with the respective method, whereas the other two datasets, the *PPMI* dataset and the *MPH* dataset were used for testing only, not for training.

### 4.1 Development dataset

The development dataset comprised 1740 consecutive DAT-SPECT from clinical routine at our site as described in [56]. In brief, DAT-SPECT with [<sup>123</sup>I]FP-CIT had been performed according to common procedures guidelines [57, 58] with different double-head cameras equipped with low-energy-high-resolution or fan-beam collimators. The projection data were reconstructed using the iterative ordered-subsets-expectation-maximization [59] with attenuation and simulation-based scatter correction as well as collimator-detector response modeling as implemented in the Hybrid Recon-Neurology tool of the Hermes SMART workstation v1.6 (Hermes Medical Solutions, Stockholm, Sweden) [60-63]. All parameter settings were as recommended by Hermes [60] for the EANM / EANM Research Ltd (EARL) ENC-DAT project (European Normal Control Database of DaTSCAN) [64-68]. More precisely, ordered-subsets-expectation-maximization was performed with 5 iterations and 15/16 subsets for 120/128 views. For noise suppression, reconstructed images were postfiltered by convolution with a 3-dimensional Gaussian kernel of 7 mm full-width-at-half-maximum. The development dataset was used for both, training and testing. For this purpose, the dataset was randomly split into ??? training cases and ??? test cases. The gold standard label as either “normal” or Parkinson-typical reduction (“reduced”) of the striatal signal had been obtained by visual interpretation of the DAT-SPECT images by 3 independent readers [56]. TODO Data augmentation (without attenuation and scatter correction, gaussian filtering): to be described.

### 4.2 External testing datasets

The second dataset comprised 645 DAT-SPECT with [<sup>123</sup>I]FP-CIT from the Parkinson’s Progression Markers Initiative (PPMI) ([www.ppmi-info.org/data](http://www.ppmi-info.org/data)) [69]. The dataset included 438 patients with Parkinson’s disease and 207 healthy controls as described in [46]. Details of the PPMI DAT-SPECT protocol are given at

<http://www.ppmi-info.org/study-design/research-documents-and-sops/> [69]. Raw projection data has been transferred to the PPMI imaging core lab for central image reconstruction using an iterative (HOSEM) algorithm on a HERMES workstation. The clinical diagnosis was used as gold standard label (Parkinson’s disease = “reduced”, healthy control = “normal”).

The third dataset (“MPH dataset”) comprised 640 consecutive DAT-SPECT with [<sup>123</sup>I]FP-CIT from clinical routine at UKE that had been acquired with a triple-head camera equipped with brain-specific multiple pinhole collimators. Multiple pinhole SPECT concurrently improves count sensitivity and spatial resolution compared to SPECT with parallel-hole and fan-beam collimators [70, 71]. The projection data were reconstructed with the Monte Carlo photon simulation engine and iterative one-step-late maximum-a-posteriori expectation-maximization implemented in the camera software (24 iterations, 2 subsets) [71, 72]. Neither attenuation nor scatter correction was applied. The gold standard label (“normal” or “reduced”) was obtained by visual interpretation by an experienced reader (about 20 years of experience in clinical DAT-SPECT reading,  $\geq 3,000$  cases). All SPECT images were interpreted twice (with different randomization) by the same reader. The delay between the reading sessions was 14 days. Cases with discrepant interpretations between the two reading sessions were read a third time by the same reader to obtain an intra-reader consensus as the gold standard label. The MPH test dataset has not been described previously.

Image characteristics were quite different between the datasets (Figure ???). Compared to the development dataset, the internal test dataset was characterized by better spatial resolution (resulting in higher striatum-to-background contrast) and less statistical noise. The external test dataset showed lower spatial resolution than the development dataset (lower striatum-to-background contrast).
